Methods & Sampling

Data was gathered experimentally at the Baruch Institute for Marine & Coastal Sciences. Wet weight (blotted (g)) of the prey items were determined before and after the trial with an analytical balance.

A total of 36 stone crabs (22 females [mean] and 14 males; CW ± SD, 90.7 ± 10.6 mm) were collected for use in the first experiment. The larger, crusher claw was removed from 19 of these stone crabs within 24 h of their capture. The crabs (each of which survived in the laboratory for several weeks) were housed in individual 5-gal buckets, each provided with a separate flowthrough seawater source, allowing water temperature and salinity to fluctuate with ambient conditions. The experiment was conducted over 4 72-h trials (blocked by time) during a 2-wk period. A control, which consisted of a bucket without a crab and the same amount of each food item, was included in each experimental block to account for any consumptionindependent changes in biomass of the provided diet items.

Each crab was provided with 6 diet options simultaneously that are commonly found in oyster reefs within North Inlet estuary: eastern oysters (Crassostrea virginica), hard clams (Mercenaria mercenaria), ribbed mussels (Geukensia demissa), green algae (Ulva spp.), red algae (Gracilaria spp.), and sun sponge (Hymeniacidon heliophila). Because of large differences in the mass-to-volume ratio between these food items, the mass and volume of the different food types provided could not standardized simultaneously. The reasoning was that crabs are consumption limited by the volume of space in the stomach, and therefore an attempt was made to standardize the relative volume of consumable tissue across diet types. They determined the amount of food consumed as the difference between the initial and the final blotted wet weight of each food item throughout the 72-h experiment. Although using wet weights is less accurate than using dry weights, it was necessary because stone crabs were fed living organisms, and the initial dry weight could not be determined without sacrificing the provided organisms. The amount of each food type consumed was analyzed using a multivariate linear mixed effects model (LMER in R), using the logarithm of wet weight consumed for each diet item as response variables, number of claws, sex, and CW as predictor variables, and trial date as a random blocking factor. This was followed by individual linear mixed-effects models using the same variables to examine each diet item separately.

Data Processing Description

Data (other than calculating the log data for plotting) has not been processed.

BCO-DMO Processing:
- added conventional header with dataset name, PI name, version date, reference information
- renamed parameters to BCO-DMO standard
- reformatted date from d-Mon-yy to yyyy-mm-dd
- replaced blank cells with nd

Parameters

Parameter	Description	Units
claw	1-clawed = Y; 2-clawed = N	unitless
date_start	date the experiment was started for each crab	yyyy-mm-dd
date_block	block that was used during statistical analysis	days
crab	subject number	unitless
carap_width	width of crab carapace at widest point	millimeters
sex	male = M; female = F	unitless
days_ACR	days after claw removal that subject was used in experiment	days
oyster_con_g	amount of wet mass of oyster (Crassostrea virginica) tissue consumed	grams
mussel_con_g	amount of wet mass of mussel (Geukensia demissa) tissue consumed	grams
clam_con_g	amount of wet mass of clam (Mercenaria mercenaria) tissue consumed	grams
sponge_con_g	amount of wet mass of sponge (Hymeniacidon heliophila) tissue consumed	grams
Ulva_con_g	amount of wet mass of Ulva sp. tissue consumed	grams
Grasc_con_g	amount of wet mass of Gracilaria sp. tissue consumed	grams
sponge_con_corr_g	amount of sponge consumed corrected for control	grams
Ulva_con_corr_g	amount of ulva consumed corrected for control	grams
Grasc_con_corr_g	amount of grascillaria consumed corrected for control	grams

Project Information

Linking Variation in Metabolic Processes as a Key to Prediction (Variation in Metabolic Processes)

Description from NSF award abstract:
A major goal of biological and ecological sciences is to understand natural systems well enough to predict how species and populations will respond to a rapidly changing world (i.e., climate change, habitat loss, etc.). A population under any conditions will grow, shrink, or disappear altogether depending on how efficiently individuals consume resources (food), utilize that food metabolically, and eventually reproduce. However, making accurate predictions based on these metabolic processes is complicated by the realities that each species has different resource requirements and that no two individuals within a species are exactly alike. Rather, individuals vary and this variation, both within and across species, is central to many ecological and evolutionary processes. Developing the ability to predict responses of biological systems to a changing world therefore requires a mechanistic understanding of variation. The goal of this project is to improve this mechanistic understanding by examining variation within a metabolic context across a range of species that have a spectrum of commonly-seen resource requirements. Further, the work capitalizes on a unique biological characteristic of this group of species that allows control and manipulation of individual reproduction, facilitating experimental study of the mechanistic links between variation in individual consumption, metabolism, and reproduction. The foundation this research is a combination of field measurements and laboratory experiments using both well-established and newly-developed techniques to quantify these links. The result will be a quantitative framework to predict how individuals will respond reproductively to changes in resource use. Because of the close link between individual reproduction and population dynamics, this research will contribute substantially to predictions in population dynamics under realistic conditions where individuals use more than a single resource, and improve the prediction of responses to current and future ecological changes.

The following publications and data resulted from this project:

Belgrad, B. and B. Griffen. 2016. Predator-prey interactions mediated by prey personality and predator identity.*Proc. Roy. Soc. B*: In Review. [2016-01-20]
P. herbstii mortality data: Mortality of crabs when exposed to either a single blue crab, toadfish, or no predator for a week
P. herbstii personality data: Refuge use of crabs when exposed to predator odor cues from either blue crabs, toadfish, or control of no cue
P. herbstii predator behavior data: Refuge use and mobility of blue crabs and toadfish while in mesocosms for a week - behavior measured during two days.

Belgrad, B. and B. Griffen. 2016. The influence of dietary shifts on fitness of the blue crab, *Callinectes sapidus*. *PloS One. DOI: 10.1371/journal.pone.0145481*.
Blue crab activity: Activity of crabs fed different diets over a summer
Blue crab egg size: Volume of eggs for crabs fed different diets
Blue crab hepatopancreas index (HSI): Weight of hepatopancreas for crabs fed different diets
Blue crab hepatopancreas lipid content: Hepatopancreas lipid content of crabs fed different diets
Blue crab reproductive tissue analysis (GSI): Gonadosomatic index of blue crabs on various diets
Blue crab survival: Blue crab survival data during the dietary study
