## Coverage

**Spatial Extent**: Lat:16.815333 Lon:-88.0815 **Temporal Extent**: 2015-05-28 - 2015-07-25

# **Dataset Description**

Distribution of new *E. lori* settlers (i.e., individuals <10mm with minimal pigment) arriving from the water column.

These data were included in Figure 9 and Table 4 of:

Majoris, JE; D'Aloia CC, Francis RK, Buston PM (Accepted) Differential persistence favors habitat preferences that determine the distribution of a reef fish. Behav. Ecol.

## Methods & Sampling

To observe the distribution of new settlers arriving from the water column, the 120 tagged sponges were cleared of settlers and then surveyed for new settlers every 24 – 48 hrs throughout two lunar cycles (28 May – 25 July 2015). We constructed a generalized linear mixed-effects model (GLMM; distribution = binomial; link = logit) using the 'lme4' package in R (Bates et al. 2015) to evaluate how habitat and social variables influence the distribution of new settlers on sponge habitat. The arrival of multiple new settlers on an individual sponge was rare. Therefore, we investigated the relationship between the presence or absence of an *E. lori* settler (0 or 1,

respectively) and all habitat and social variables. Sponge ID was included as a random effect to control for repeated observations of the same 120 tagged sponges.

# **Data Processing Description**

R version 3.2.3

## **BCO-DMO Data Processing Notes:**

- dates reformatted to yyyy/mm/dd
- periods replaced with underscores in column names
- missing identifier replaced with nd

## **Parameters**

| Parameter  | Description                                      | Units    |
|------------|--|----------|
| Date       | Date of observation; YYYY/MM/DD                  | unitless |
| Lunar_day  | Day in lunar cycle                               | day      |
| Sp_ID      | Tag number from 1 - 120 used to identify sponges | unitless |
| Sp_depth   | Depth at base of the spongein feet               | feet     |
| Sp_depth_m | Depth at base of the sponge in meters            | meters   |

| Sponge species: Aplysina fistularis (Y); or Agelas conifera (B)   | unitless  |
|---|---|
| Maximum tube length of sponge   |   |
| Number of sponge tubes greater than 10 centimeters  |   |
| Residents presence (1) or absence (0)   | unitless  |
| Number of residents observed on each sponge   |   |
| Reproduction (ie: clutch) present (1) or absent (0)   | unitless  |
| New settler presence (1) or absence (0) on a tagged sponge (i.e. individuals less than 10mm with minimal pigmentation that settled to the sponge from the water column)                     |   |
| Number of new settlers observed on a tagged sponge  | number  |
| Standard length of new settlers on sponge   |   |
| Standard length of new settlers on sponge   | millimeters   |
| Standard length of new settlers on sponge   |   |
| Standard length of new settlers on sponge   | millimeters   |
| Post-settler presence (1) or absence (0) on a tagged sponge (i.e. E. lori individuals 10mm or greater but 18mm or less standard length that moved to the sponge from elsewhere on the reef) |   |
| Number of post-settlers observed on a tagged sponge   |   |
| Standard length of post-settlers  | millimeters   |
| Standard length of post-settlers  | millimeters   |
| Standard length of post-settlers  | millimeters   |
|   | Maximum tube length of sponge  Number of sponge tubes greater than 10 centimeters  Residents presence (1) or absence (0)  Number of residents observed on each sponge  Reproduction (ie: clutch) present (1) or absent (0)  New settler presence (1) or absence (0) on a tagged sponge (i.e. individuals less than 10mm with minimal pigmentation that settled to the sponge from the water column)  Number of new settlers observed on a tagged sponge  Standard length of new settlers on sponge  Post-settler presence (1) or absence (0) on a tagged sponge (i.e. E. lori individuals 10mm or greater but 18mm or less standard length that moved to the sponge from elsewhere on the reef)  Number of post-settlers observed on a tagged sponge  Standard length of post-settlers  Standard length of post-settlers |

## **Project Information**

Collaborative Research: The Role of Larval Orientation Behavior in Determining Population Connectivity (Elacatinus Dispersal II)

Coverage: Belizean Barrier Reef System

#### Description from NSF award abstract:

Understanding how far young fish move away from their parents is a major goal of marine ecology because this dispersal can make connections between distinct populations and thus influence population size and dynamics. Understanding the drivers of population dynamics is, in turn, essential for effective fisheries management. Marine ecologists have used two different approaches to understand how fish populations are connected: genetic methods that measure connectivity and oceanographic models that predict connectivity. There is, however, a mismatch between the predictions of oceanographic models and the observations of genetic methods. It is thought that this mismatch is caused by the behavior of the young, or larval, fish. The objective of this research is to study the orientation capabilities of larval fish in the wild throughout development and under a variety of environmental conditions to see if the gap between observations and predictions of population connectivity can be resolved. The project will have broader impacts in three key areas: integration of research and teaching by training young scientists at multiple levels; broadening participation of undergraduates from underrepresented groups; and wide dissemination of results through development of a website with information and resources in English and Spanish.

The overall objective of the research is to investigate the role of larval orientation behavior throughout ontogeny in determining population connectivity. This will be done using the neon goby, Elacatinus lori, as a model system in Belize. The choice of study system is motivated by the fact that direct genetic methods have already been used to describe the complete dispersal kernel for this species, and these observations indicate that dispersal is less extensive than predicted by a high-resolution biophysical model; E. lori can be reared in the lab from hatching to settlement providing a reliable source of larvae of all ages for proposed experiments; and a new, proven behavioral observation platform, the Drifting In Situ Chamber (DISC), allows measurements of larval orientation behavior in open water. The project has three specific objectives: to understand ontogenetic changes in larval orientation capabilities by correlating larval orientation behavior with developmental sensory anatomy; to analyze variation in the precision of larval orientation in different environmental contexts through ontogeny; and to test alternative hypotheses for the goal of larval orientation behavior, i.e., to determine where larvae are heading as they develop.
